

Import data using transform map using spread sheet

Detailed Architecture

1. Data Source Layer

The HR Admin provides an Excel spreadsheet containing employee information. The spreadsheet includes Employee ID, Name, Email, Department, and Location.

2. Staging Layer

The spreadsheet is imported into the **Import Set Table**. This table acts as a temporary staging area where the imported data can be checked before it reaches the Employee table.

3. Transformation Layer

A **Transform Map** defines how each spreadsheet column maps to the corresponding field in the Employee table. For example, the spreadsheet's Employee ID is mapped to the Employee ID field.

4. Identification Layer

The system uses **Employee ID as the unique identifier/coalesce field**. It checks whether the Employee ID already exists in the target Employee table.

5. Decision Layer

If the Employee ID is found, the system **updates the existing employee record**. If the Employee ID is not found, the system **creates a new employee record**.

6. Target Layer

After successful transformation, the final employee information is stored in the **Employee table** and can be viewed and managed in ServiceNow.
